# Key Messages

Draft IRP 2018 is a very different plan to the Draft IRP 2016 and establishes solid principles

VRE (PV and wind) with flexibility\(^1\) confirmed as least-cost energy mix as existing coal fleet decommissions; This energy mix also exhibits the least CO\(_2\) emissions and least water usage

Demand growth impacts the timing of new-build capacity but energy mix remains largely unchanged

New-build coal only post-2030 if CO\(_2\) emissions are not too restrictive and new-build VRE is constrained

New-build nuclear only post-2030 if CO\(_2\) emission are restrictive and new-build VRE is constrained

---

\(^1\) Natural gas fired peaking and mid-merit capacity considered as a proxy for this.

NG - Natural gas; PV – Solar Photovoltaics; VRE – Variable renewable energy; EAF – Energy Availability Factor; RoCoF – Rate of Change of Frequency
Key Messages

To 2030 - outcomes similar across most scenarios but notable risks; Eskom coal fleet EAF (and decommissioning schedule), completion of new-build coal, stationary storage and DSR

To 2030, in the Recommended Plan, expect net employment increase (as system grows) but net decrease in coal

Post 2030 - key drivers include VRE new build limits, decommissioning, demand growth, stationary storage

Natural gas risk relatively small and can be replaced by appropriate domestic flexibility sources or stationary storage

No system integration issues foreseen pre-2030 but an informed and co-ordinated work program is necessary to sufficiently prepare for post-2030 relatively high VRE penetration levels

1 Natural gas fired peaking and mid-merit capacity considered as a proxy for this.
NG - Natural gas; PV – Solar Photovoltaics; VRE – Variable renewable energy; EAF – Energy Availability Factor; RoCoF – Rate of Change of Frequency
At a glance

Previous CSIR contributions have notably impacted and are mentioned throughout the Draft IRP 2018

- Demand forecast: CSIR (Built Environment) provide this as an input to DoE

- Principles raised by CSIR comments on Draft IRP 2016 have been explicitly considered

- These were: New-build limits removed (IRP1), RE costs aligned with REIPPPP, least-cost Base Case established

CSIR have engaged with key stakeholders in the 60 day public consultation period

- Bilateral engagements: DoE, SALGA, EIUG, Nersa, Eskom

- Attendance at IRP workshops: EE Publishers, FFF, NIASA (requested feedback)

- Tentative: Parliament Portfolio Committee (Energy)
Draft IRP 2018 scenario summaries – this is a very different plan to the Draft IRP 2016 and establishes solid principles

• Least-cost confirmed as combination of PV, wind and flexible capacity\(^1\) as coal decommissions – also exhibits lowest CO\(_2\) emissions and water usage by 2050

• Technology new-build limits (PV, wind) mean post-2030 deployment is constrained with new-build coal and gas replacing it (assuming less restrictive CO\(_2\) constraints)

• Higher NG price means less NG usage (notable capacity for system adequacy) and increased new-build coal

• More strict CO\(_2\) emissions (Carbon Budget) with RE new-build limits means less new-build coal and deployment of nuclear instead

• Higher NG price and more strict CO\(_2\) emissions (Carbon Budget) with RE new-build limits means less NG and coal, increased nuclear instead

• Higher/Lower demand forecast means same mix of new-build of PV, wind and flexibility\(^1\) just earlier/later

---
\(^1\) Natural gas fired peaking and mid-merit capacity considered as a proxy for this; NG - Natural gas; PV – Solar Photovoltaics
Energy mix by 2030 similar across scenarios as coal dominates, IRP1 is ≈R10bn/yr cheaper than next best IRP3, IRP7 lowest CO$_2$ emissions

2030

At a glance

Jobs impact of Recommended Plan – reduced role of coal whilst growth in other sectors is expected

- If the Recommended Plan is implemented, there is an employment reduction expected in coal pre-2030
- Overall jobs grow as the power system grows – in solar PV, wind and gas sectors
- This transition needs sufficient preparation – our comments attempt to assist to quantify effects
Net reduction of jobs in coal of ≈100k but net gain overall as gas grows to ≈55k jobs towards 2030, RE contributes up to ≈110k by 2030

Sources: Draft IRP 2018; CSIR Energy Centre analysis
Note: Job potential includes direct, indirect and induced jobs; Nuclear is estimated based on existing experience at Koeberg (KPMG, 2017)
At a glance

Key energy planning risks – Existing fleet low EAF, stationary storage, DSR, further RE learning

- Existing fleet Low EAF: Earlier new-build (2023), outcomes return to IRP1 if low demand and low coal fleet performance
- Storage: Decreasing stationary storage costs (batteries) results in deployment pre-2030, less NG usage and increased solar PV
- DSR: A more responsive demand-side test via electric water heating and EVs delays some capacity investment and deploys slightly more solar PV
- Further RE learning: Increased solar PV and wind post-2030 with timing pre-2030 unchanged, no import hydro
- A risk adjusted scenario: Combining storage, DSR and further RE learning results in increased new-build wind, PV, storage and further lower NG use

EAF – Energy Availability Factor; DSR – Demand Side Response; Evs – Electric Vehicles
Sources: Eskom; Tesla; BNEF; CSIR
Draft IRP 2018 (IRP1) - Least-cost deploys considerable wind, solar PV and NG capacity to 2030 and beyond as the coal fleet decommissions

Installed capacity and electricity supplied from 2016 to 2050 as planned in the Draft IRP 2018

Draft IRP 2018 IRP1 with storage, DSR and lower RE costs results in increased new-build wind, solar PV, storage and less NG

Installed capacity and electricity supplied from 2016 to 2050 for IRP1 with storage, DSR and higher RE cost reductions

Notes: NG = Natural gas
Sources: Draft IRP 2018. CSIR Energy Centre analysis
Risk-adjusted scenario with Low EAF requires earlier new-build around 2023 too and increased absolute levels of new-build by 2030

Installed capacity and electricity supplied from 2016 to 2050 for Risk-adjusted scenario with low coal fleet EAF

**Installed capacity**

**Energy mix**

**Electricity production**

**First new-builds:**
- **PV (2023)**: 0.4 GW
- **Wind (2023)**: 0.2 GW
- **OCGT (2023)**: 1.9 GW

Sources: Draft IRP 2018, CSIR Energy Centre analysis
At a glance

Descriptive inputs/comments – new-build limits, NG import risk and embedded generation

• Technology new-build limits: Still unjustified, constant as power system grows, misaligned with international experience today

• Coal capacity: Investigations reveal that older existing coal capacity could be decommissioned earlier, parts of under construction capacity could be replaced by alternatives and it is not economically optimal to build new coal

• Natural gas import risk: Small role in energy mix (up to 5% pre-2030, 15% by 2050) - can be mitigated by range of domestic options (as well as stationary storage if costs decline)

• Embedded generation: Planning for this is not yet explicit and will need to change (implicit as negative demand)

• Demand profile will change further as different sectors grow, use energy differently and deploy EG for self-use
System services and technical considerations

• System adequacy consistent across all scenarios i.e. reserve requirements included

• System non-synchronous penetration: No barriers pre-2030. Only above 25% from 2028 and 37% by 2030 for 10% of the time but at above 80% by 2050 i.e. system integration focus becomes important post-2030

• A critical indicator (inertia): No barriers pre-2030. Post-2030 worst case mitigating solution cost is ≈1% of total system cost

• Evolution of other system services need to be investigated for post-2030 transition expected (reactive power and voltage control, system strength)

• Variable resource forecasting will become more important - SO should be equipped will relevant tools and skills
## Improvements for future IRPs

</tbody>
</table>
## Going forward – Recommendations

### Long-term – structural and strategic

- Formally establishing a set of links/triggers between IRP and MTS AO processes (or equivalent)
  Periodic updating of the IRP should be prioritised to address dynamic planning environment

- Further understanding just transition to address labour and socio-economic impacts in the energy sector

- Integrating national and local level energy planning for improved co-ordination and leveraging of opportunities

- Sector-coupling opportunities across the full energy sector (not just electricity)

- Investigate approaches to include geospatial component of IRP – supply/network/demand (co-optimisation)

- Further investigations into impacts/opportunities of new/emerging technologies e.g. stationary storage, EVs, DSR
Formal comments on Draft IRP 2018

1 Executive Summary

2 Background

3 Draft IRP 2018 scenarios

4 Draft IRP 2018 employment impacts

5 Draft IRP 2018 energy planning risks

6 System services and technical considerations
Integrated Resource Plan (IRP): Process for power generation capacity expansion in South Africa

Inputs
1) Demand Forecast
2) Existing Supply Forecast:
   - Plants under construction
   - Preferred bidders
   - Decommissioning
   - Plant performance
3) New Supply Options:
   - Technology costs
     assumptions
   - Technology technical characteristics
4) Constraints:
   - CO₂ limits
   - Security/adequacy of supply level

IRP modelling framework (PLEXOS®)
- LT¹ techno-economic least-cost optimisation
- MT/ST² production cost testing system adequacy (security of supply)

Output
- Per scenario:
  - Total system costs
  - Capacity expansion (GW)
  - Energy share (TWh)
  - CO₂ emissions
  - Water usage
  - Jobs in the electricity sector
- After policy adjustment:
  - Final “IRP” for promulgation
  - Key questions answered:
    - What to build (MW)?
    - When to build it (timing)?

Procurement
- (competitive tender e.g. REIPPPP, coal IPPPP)

Outcomes
- Preferred bidders
- MW allocation
- Technology costs actuals (Ø IPP tariffs)

1 LT = Long-term
2 MT/ST = Medium-term/Short-term

Planning / simulation world

Actuals / real world
The IRP currently optimises for the dominant generation costs, system reserves (adequacy) and shallow grid cost components of total system cost.

**Optimised in PLEXOS model**
- Generation (Gx)
- Tx network (shallow)
- System services (reserves)
- Tx network (deep)
- System services (other)
- Distribution network (Dx)
- Other (metering, billing, customer services, overheads)

**Not optimised in PLEXOS modelling framework**
- Not considered
- Partially considered previously (quantified for system inertia)
- Not considered
- Not considered

**Costs included in optimisation model:**
- CAPEX (plant level)
- FOM¹
- VOM²
- Fuel
- Shallow grid connection costs

**Costs excluded in optimisation model:**
- Gx: Externalities e.g. CO₂ emissions costs
- Gx: Decommissioning costs
- Gx: Waste management and/or rehabilitation
- Gx: Major mid-life overhaul
- Tx: Deep costs
- Other system services
- Dx: Distribution network costs
- Other costs

¹ FOM = Fixed Operations and Maintenance costs; ² VOM = Variable Operations and Maintenance costs; ³ Typically referred to as Ancillary Services includes services to ensure frequency stability, transient stability, provide reactive power/voltage control, ensure black start capability and system operator costs.
IRP process as described in the Department of Energy’s Draft IRP 2016 document: least-cost Base Case is derived from technical planning facts

Const. - Constant, Market - Natural gas linked to IEA expected market price
PPD - Peak Plateau Decline, CB - Carbon Budget
Draft IRP 2018 (IRP1) - Least-cost deploys considerable wind, solar PV and NG capacity to 2030 and beyond as the coal fleet decommissions

Installed capacity and electricity supplied from 2016 to 2050 as planned in the Draft IRP 2018

Submitted to DoE on 25 October 2018

Sources: Draft IRP 2018. CSIR Energy Centre analysis
Draft IRP 2018 (IRP3) – RE new-build limits mean post-2030 deployment of solar PV and wind is constrained with new-build coal and gas replacing it.

Installed capacity and electricity supplied from 2016 to 2050 as planned in the Draft IRP 2018.

Sources: Draft IRP 2018. CSIR Energy Centre analysis.
Draft IRP 2018 (IRP5) – Market linked NG price means in less NG usage, notable capacity for system adequacy and increased new-build coal

Installed capacity and electricity supplied from 2016 to 2050 as planned in the Draft IRP 2018

Sources: Draft IRP 2018. CSIR Energy Centre analysis
Draft IRP 2018 (IRP6) – Carbon Budget limits new-build coal capacity and deploys new-build nuclear capacity instead

Installed capacity and electricity supplied from 2016 to 2050 as planned in the Draft IRP 2018

Formal comments on Draft IRP 2018

1 Executive Summary
2 Background
3 Draft IRP 2018 scenarios
4 Draft IRP 2018 employment impacts
5 Draft IRP 2018 energy planning risks
6 System services and technical considerations
The International Jobs and Economic Development Impacts (I-JEDI) model is a freely available economic tool to understand economic changes (jobs focus at this stage) for energy technology choices.

I-JEDI has been customised for application to the South African environment by the CSIR team.

CSIR utilised the developed I-JEDI tool for South Africa to assess the Recommended Plan in the Draft IRP 2018 for a range of technologies including wind, solar, coal and natural gas (for now)... more in future.

High-level approach

- I-JEDI estimates economic impacts by characterising construction and operation of energy projects in terms of expenditures and portion of these made within the country (localised).
- These are then used in a country-specific input-output (I-O) model to estimate employment (amongst a range of other metrics).

An indicative analysis of jobs in nuclear is also provided (but not based on I-JEDI for now).

Analysis of other Draft IRP 2018 scenarios as well as those presented by CSIR to come¹

¹ Time available was not sufficient to do this in the 60 day public consultation period.
Sources: https://www.nrel.gov/analysis/jedi/about.html
Coal dominant in jobs (as expected) but declines to 2030 in Recommended Plan as gas grows, notable gap for wind and PV

Sources: Draft IRP 2018; CSIR Energy Centre analysis
Note: Job potential includes direct, indirect and induced jobs; Nuclear is estimated based on existing experience at Koeberg (KPMG, 2017)
Net job decrease in coal of ≈100k but net gain overall as gas grows to ≈55k jobs towards 2030, RE contributes up to ≈110k by 2030

Sources: Draft IRP 2018; CSIR Energy Centre analysis
Note: Job potential includes direct, indirect and induced jobs; Nuclear is estimated based on existing experience at Koeberg (KPMG, 2017)
Focus on coal: Emphasising impact of construction jobs via new-build (excl. Medupi/Kusile) and net decline in operations jobs to 2030

Sources: Draft IRP 2018; CSIR Energy Centre analysis
Note: Job potential includes direct, indirect and induced jobs
Net job losses in coal overall of ≈100k, direct jobs in coal shifting from ≈80k in 2016 to ≈50k by 2030

Sources: Draft IRP 2018; CSIR Energy Centre analysis
Note: Job potential includes direct, indirect and induced jobs

      e Existing coal fleet performance
   5.2 Descriptive comments
6 System services and technical considerations
Impact of stationary storage (scenario)

In the Draft IRP 2018 – no cost reductions are considered for stationary storage

What if stationary storage costs start to decline?
Stationary storage (excl. pumped storage):
200 $/kWh (2030), 150 $/kWh (2040), 100 $/kWh (2050)

Overnight capital cost [R/kWh]
(Jan-2017-Rand)

---

Sources: StatsSA for CPI; Draft IRP 2018; CSIR; BNEF; CSIRO (2015); Nykvist (2015); IDC; IRENA (2017)

USD:ZAR = 14.00; NOTE: Battery packs are assumed to make up 60% of total utility-scale stationary storage costs (from BNEF).
Draft IRP 2018 IRP1 with storage cost declines means notably less NG, with storage deployed from 2027, increased solar PV and wind.

Installed capacity and electricity supplied from 2016 to 2030 as planned in the Draft IRP 2018.

Total system cost: IRP1 with storage cost declines ≈ R8 bn/year less expensive by 2050 than IRP1, marginal difference before 2030

Note: Average tariff projections (and resulting total system cost) consider an offset representative of Tx/Dx/Other costs to align with starting point of 0.84 ZAR/kWh (0.20 ZAR/kWh). From 2017 to 2018, immediate cost reflectivity is considered too (as in Draft IRP 2018) i.e. 0.21 ZAR/kWh offset.

Formal comments on Draft IRP 2018

1 Executive Summary
2 Background
3 Draft IRP 2018 scenarios
4 Draft IRP 2018 employment impacts
5 Draft IRP 2018 energy planning risks
   5.1 Scenarios
      a Impact of stationary storage
      b Impact of Demand Side Response (DSR)
      c Technology learning
      d Risk-adjusted scenario
      e Existing coal fleet performance
6 System services and technical considerations
Impact of demand response - EVs, warm water heating (scenario)

What if the demand side became more flexible and responsive i.e. Demand Side Response (DSR)

Similar to previous comments in Draft IRP 2016 with some updated analysis on DSR options

Warm-water heating (geysers)
Electric vehicles
Majority of EV owners charge vehicles overnight in off-peak – this will have a relatively small impact on demand profile (beyond 2030)

Typical EV charging profiles

Impact of typical EV charging on RSA demand profile

NOTE: EVs assumed only light passenger vehicles for now.
Electric vehicle usage for demand side flexibility
i.e. Vehicle-to-Grid (V2G)

Inclusion of a demand side flexibility resource in the form of mobile storage (electric motor vehicles) demonstrates impact on the power system as adoption increases.

Considered with similar functionality as that of Electric Water Heating (EWH) demand shaping - a resource with intra-day controllability (can be dispatched as needed on any given day) based on power system needs i.e. vehicle-to-grid (V2G)

Key input parameters to estimate potential demand shaping via electric motor vehicles:
- Current population
- Expected population growth to 2050
- Current number of motor vehicles
- Expected motor vehicles per capita
- Adoption rate of electric vehicles to 2050
- Electric vehicle fleet capacity (MW)
- Electric vehicle energy requirement (GWh/d)
- Proportion of electric vehicle fleet connected simultaneously
Electric vehicle demand shaping can provide ~96 GW/4.2 GW (demand increase/decrease) with ~40 GWh/d of dispatchable energy by 2050

Sources: CSIR estimates; StatsSA; eNaTis
Demand shaping as a demand side resource - domestic electric heaters (EWHs)

Many opportunities for demand shaping in a number of end-use sectors (domestic, commercial, industrial)

In the scenarios assessed by CSIR - the intention of including one particular demand shaping opportunity (domestic electric water heating) is to demonstrate the significant impact this can have on the power system.

Modelled as a resource with intra-day controllability (can be dispatched as needed on any given day) based on power system needs

Key input parameters to estimate potential demand shaping via EWH:

- South African population (to 2050)
- Number of households (current)
- Number of persons per household (future)
- EWHs (current)
- EWHs per household (future)
- Adoption rate of demand shaping via EWHs (future)
- Calibration for power (MW) and energy (TWh) used for electric water heating (existing)
- Movement to EWH technologies i.e. heat pumps vs electric geysers (future)
Demand shaping can provide ~24 GW/3 GW (demand increase/decrease) with ~70 GWh/d of dispatchable energy by 2050

Note: Average tariff projections (and resulting total system cost) consider an offset representative of Tx/Dx/Other costs to align with starting point of 0.84 ZAR/kWh (0.20 ZAR/kWh). From 2017 to 2018, immediate cost reflectivity is considered too (as in Draft IRP 2018) i.e. 0.21 ZAR/kWh offset.

Sources: Draft IRP 2018. CSIR Energy Centre analysis. Eskom on Tx, Dx costs
Generally – additional EV demand met by least-cost mix of wind, solar PV and gas whilst V2G shifts this mix more towards solar PV and less gas

Impact on least-cost capacity mix

**EVs typical configuration**  
(G2V i.e. additional demand)

- For 1-mln EVs, increase of ≈3 TWh/yr
- For 1-mln EVs, increase ≈1 GW peak demand
- New build capacity to meet charging demand is mostly wind, solar PV and gas
- Most charging demand met by wind and gas

**EVs as a demand shaping resource**  
(V2G i.e. implicit in demand)

- Increase in proportion of new solar PV vs. wind
- Less gas capacity i.e. lower gas energy share
- Relative reduction in total system cost

---

**G2V - Grid to vehicle**  
**V2G - Vehicle to grid**

6 System services and technical considerations
Draft IRP 2018 investigated implications of unconstrained least-cost (IRP1) but RE new-build limits are maintained for all other scenarios

“The scenario without new-build limits provides the least-cost option by 2030”

“Imposing new-build limits on RE will not affect the total installed capacity and the energy mix for the period up to 2030”

“The scenario without RE annual build limits provides the least-cost option by 2050”

“The scenario without RE annual build limits provides the least-cost electricity path to 2050”

Why new-build limits (on any technology – needs justification)?

Could be various reasons

• Import/transport link limitations (infrastructure – ports, roads)
• Industry ability to deliver (skills, development, construction)
• Available Tx/Dx networks to evacuate power
• System security/stability
Draft IRP 2018 RE annual new-build limits have thusfar not been justified

New-build limits on technologies means no more than these limits are allowed to be built in any given year

Limits have been applied to two technologies (others unlimited):
  Solar PV
  Wind

Limits are constant as power system grows

No justification provided for these limits

Sources: Scatec; Hopefield
Solar PV is limited to 1000 MW annually resulting in a move from 2.5% of peak demand in 2020 to 1.7% of peak demand by 2050.

Sources: Eskom; Draft IRP 2018; CSIR analysis
Wind is limited to 1600 MW annually resulting in a move from 4.0% of peak demand in 2020 to 2.7% of peak demand by 2050.

Sources: Eskom; Draft IRP 2018; CSIR analysis
Already happening: Both leader, follower and 2nd wave countries installing more new solar PV per year than South Africa’s IRP limits for 2030/2050

6 System services and technical considerations
Even currently under-construction and committed capacity will be part of planned decommissioning and will require new-build.
New-build largely driven by the planned decommissioning of the existing coal fleet - mostly post 2030

Sources: Draft IRP 2018; CSIR analysis
Should we freely optimise the decommissioning of the existing coal fleet or finish the last 2 units at Kusile?

Should we build new coal capacity in South Africa?

Should a freely optimised existing coal fleet be decommissioned any earlier/later?

Should the last 2 units at Kusile be completed in light of alternatives?

This has been studied in previous work

Summary of outcomes are presented here for reference
System Alternate Value (SAV) approach attempts to obtain the present value of a power station over the full time horizon.
Early decommissioning of oldest selected coal-fired power stations would result in significant savings and a cheaper power system.

Max. allowed equivalent capex cost of remaining 2 Kusile units

Need for natural gas: Understanding domestic natural gas options

Natural gas source not critical in IRP at this stage but... whether it is domestic/imported is important

What is the energy security risk of importing all of the natural gas required in Draft IRP 2018 scenarios?

Sources: PetroSA; Eskom; Excellerate
The role of natural gas in the energy mix (likely via imported LNG at this stage) is relatively small to 2030 (2-5%) and up to 15% by 2050.

**Domestic sources of flexibility and/or storage could replace some/all of these relatively small volumes of (imported) natural gas in the electricity sector**
e.g. UCG, CBM, shale gas, offshore, hydrogen, DSR, biomass/-gas, CSP, storage (pumped, batteries)
Total system cost contribution of NG fuel requirements (likely via imported LNG at this stage) is 2-4% to 2030 and up to 10% by 2050.

Just 5 years ago – power generation capacity was concentrated around Mpumalanga (coal) with some hydro, peaking and nuclear.
By 2018 – generation capacity (albeit still small) has already started to distribute across the country - not only in Mpumalanga anymore.

Sources: Eskom; CSIR analysis
IRP meets energy demand for RSA – expressed as equivalent demand (assumes EG as reduced demand)

Other (Gx)

Customers (Dom/Com/Ind)

Customers (Dom/Com/Ind)

EG (Gx)

EG (Gx)

EG = Embedded Generation; Gx = Generation; Tx = Transmission; Dx = Distribution
1 Power generated less power station load; Minus pumping load (Eskom owned pumped storage); 2 Transmission/distribution networks incur losses before delivery to customers
From Jan-Dec 2016, 234 TWh of net electricity was sent out in SA with imports of almost 11 TWh means system load was 245 TWh
Actuals captured in wholesale market for Jan-Dec 2016 (i.e. without embedded plants)

Notes: “Net Sent Out” = Total domestic generation (less auxiliary load) minus pumping load of Eskom pumped storage stations (not shown seperately)
Sources: Eskom; Statistics South Africa
IRP 2018 expects demand growth to be more certain, slower - average growth from 2016 of 1.2-2.0%/yr to 2030, 1.2-1.7%/yr to 2050

Sources: StatsSA; Draft IRP 2018
"Due to the limited data at present and for the purpose of this IRP Update, these developments were not modelled as standalone scenarios, but considered to be covered in the low-demand scenario. The assumption was that the impact of these would be lower demand in relation to the median forecast demand projection."

[DoE, Draft IRP 2018, pp. 21 of 75]

In the Draft IRP 2018, it is clearly stated that the relative to the Median demand forecast, the Lower demand forecast is representative of a combination of:

- Embedded Generation (likely mostly solar PV)
- Energy efficiency (EE)
- Fuel switching

Growth of embedded generation (EG) market being implicitly included can then be calculated based on:

- Share of EG in the difference between Median and Lower demand forecasts
- Almost all EG will likely be solar PV (with associated capacity factor)
Between 1.1 - 5.8 GW of embedded generation (assumed to be PV dominated) is implicitly considered in the Draft IRP 2018 by 2030.

      e Demand profile

6 System services and technical considerations
Demand profile is assumed unchanged in Draft IRP 2018 – updated approaches to demand profile will need to be pursued in future

Demand profile will change as constituent components of the demand forecast change

Not just purely an energy demand forecast and fitted peak load (assuming similar demand profile)

Updated approaches will be required linking with EG to ensure sufficiently accurate capacity expansion
Change in demand profile will result in very different capacity expansion options

3 Draft IRP 2018 scenarios
4 Draft IRP 2018 employment impacts
5 Draft IRP 2018 energy planning risks
6 System services and technical considerations

6.1 Networks

6.2 System services
Good to include shallow grid connection costs explicitly in Draft IRP 2018 based on extensive grid planning experience at Eskom

Draft IRP 2018 includes collector network costs in the various Eskom Customer Load Networks (CLNs) as well as shallow grid connection costs for VRE (solar PV and wind) and all other technologies

This is a welcome inclusion and is a good starting point to start to incorporate technology specific network costs previously not considered

Good objectives:

- Avoid premature congestion at Eskom Main Transmission Substations (MTSs)
- Minimising absolute number of MTSs
- Connect more smaller VRE plants in a specific area
- Allow more orderly network development and increased utilisation i.e. more efficient integration

Network costs based on unitised costing of individual equipment

Transmission substations, Satellite stations, Transformers, Transmission/Distribution bays, Overhead lines, Static VAr Compensators (SVCs)
Deep network costs are not included in Irp but covered as part of periodic and well established TDP and SGP developed by Eskom

Deep network costs (backbone strengthening) not included in Draft IRP 2018 (or any previous IRP iteration) but instead established based on periodic TDPs and SGPs developed by Eskom Grid Planning.

What is most important is how these deep network costs change on a relative basis across scenarios.

Generally, these costs do not change significantly across scenarios and thus would not materially impact least-cost outcomes.

In future iterations of the IRP, there should be a continued pursuit to include geospatial components of supply, networks and demand side options (co-optimisation) where feasible and tractable.

TDP – Transmission Development Plan; SGP – Strategic Grid Plan
6.2 System services

   a RoCoF and frequency stability
Formal comments on Draft IRP 2018

1 Executive Summary
2 Background
3 Draft IRP 2018 scenarios
4 Draft IRP 2018 employment impacts
5 Draft IRP 2018 energy planning risks
6 System services and technical considerations
   6.1 Networks
   6.2 System services
       a RoCoF and frequency stability
System services and ensuring security of supply to enable any range of future energy mixes

System services and security of supply

Frequency stability/control (system inertia and RoCoF) – *particular focus in these comments*

Transient stability and fault level (system strength)

Voltage and reactive power control

Variable resource forecasting

*All of these should inform a programme of research and effort required by all key stakeholders to ensure any future energy mix is secure*
System operators are managing high non-synchronous penetration – Ireland SNSP limits and services to manage low inertia power systems

\[ \text{SNSP [\%]} = \frac{\text{System Non-Synchronous Penetration}}{\text{Wind/PV + Imports}} \] \[\frac{\text{Demand + Exports}}{\text{(Wind/PV + Imports)/(Demand + Exports)}}\]
Averaging window is important – for frequency stability typically a 500 ms averaging window for RoCoF is considered.

The RoCoF should not exceed a particular threshold within the pre-defined averaging window e.g. 500 ms.
The demand for system inertia is driven by two assumptions: the maximum allowable RoCoF & the largest assumed system contingency

**Key assumptions:**
- Maximum allowed $RoCoF$: 0.5 Hz/s
- Largest contingency ($P_{cont}$): 2,400 MW
- Kinetic energy lost in contingency event $E_{kin(cont.)}$: 5,000 MWs

\[
E_{kin.(min)} = P_{cont} \cdot \frac{f_n}{2(RoCoF)} + E_{kin(cont.)}
\]

Term “inertia” is used a bit loosely to describe the amount of kinetic energy that is stored in the rotating masses of all synchronously connected power generators (and loads to be precise)

\[f_n = \text{System frequency} = 50 \text{ Hz}\]

**Demand for inertia**

124,800 MW.s of system inertia are required at any given point in time in order for RoCoF to stay below 0.5 Hz/s in the first 500 ms after the largest system contingency occurred

Sources: P. Kundur, Power System Stability and Control, 1994
As a starting point – we have assessed system inertia on an hourly basis via UCED in PLEXOS and some high level assumptions. Depending on what mix of power stations is operational at any given point in time, the total actual system inertia will be different.

For example, if 20 GW of old coal, 10 GW of new coal and 2 GW of nuclear are online, system inertia is:

\[
\approx 20 \text{ GW} \times 4 \text{ MWs/MVA} + 10 \text{ GW} \times 2 \text{ MWs/MVA} + 2 \text{ GW} \times 5 \text{ MWs/MVA}
\]

\[
= 110,000 \text{ MWs}
\]

If wind, PV and 5 GW of CCGTs are online, system inertia is only 47,000 MW.s

---

**Technology** | **Inertia constant [MWs/MVA]**
--- | ---
Coal (old) | 4.0
Coal (new) | 2.0
OCGT/ICE | 6.0
CCGT/CC-GE | 6.0
Biomass | 2.0
Hydro/PS | 3.0
Imports | 0.0
Nuclear | 5.0
Wind | 0.0
PV | 0.0
CSP | 2.0
DR | 0.0

SNSP levels in IRP1 of Draft IRP 2018 only above 25% from 2028 and 37% by 2030 for 10% of the time but above 80% by 2050.
System synchronous energy for IRP1 – confirmation that the power system really does only start to change until after 2030
Minimal cost of ensuring acceptable RoCoF levels even at very high non-synchronous generation penetration levels

The worst-case cost to ensure RoCoF levels are acceptable post-2030 is at most ≈1% of total system costs
Thank you
